Effect of Vermicompost and Calcium silicate to reduce the Soil Salinity on Growth and Oil determinations of Marjoram plant

Maie Mohsen M. A., Hanaa A. Abo-Kora and Abeer. Kassem H. M.

Abstract: This study was carried out during the two successive growing seasons of 2012/2013 and 2013/2014 at the farm of Soils, Water and Environ. Res. Inst., Agric. Res. Center in Sahel El-Hossynia Agric. Res. Station Farm in EL-Sharkia Governorate; Egypt, to investigate effects of vermicompost at 0, 6.8 and 10 m³/fed. on growth, essential oil %, essential oil components and chemical composition of marjoram (Majorana hortensis L.) at four levels of calcium silicate at (0, 10, 15and 20 kg/fed). Gradual and significant increases in plant height, number of branches, fresh & dry weights per plant, essential oil percentage, and essential oil yield per plant were recorded with vermicompost at 8 m³/fed. Also, 8 m³/fed. vermicompost produced the highest percentages of main components of the essential oil (Linalool, Terpinen-4-ol, β-Phyllandrene and Limonene). While the highest percentages of Sabinene and α-Phyllandrene resulted under the effect of 10m³/fed vermicompost. Also, vermicompost treatments increased total carbohydrates%, nitrogenase and dehydrogenase activities and nutrient contents of N, P, K and Ca. While reduced the Na and proline content compared to the control.

As for calcium silicate (CaSiO₃) enhanced the above mentioned traits of growth and essential oil. The highest percentages of Linalool, Terpinen-4-ol, β-Phyllandrene and Limonene were recorded in essential oil extracted from plants treated with CaSiO₃ at 15 kg/fed. While the highest percentages of Sabinene and α-Phyllandrene resulted under the effect of 20 kg/fed CaSiO₃ comparing to control. On the other hand, the lowest percentages of Linalool, Terpinen-4-ol and β-Phyllandrene resulted under the treatment with 15 kg/fed CaSiO₃. In addition that, the treatment of CaSiO₃ at 15 kg/fed. increased total carbohydrates%, nitrogenase and dehydrogenase activities and nutrient contents of N, P, K and Ca but decreased Na content and proline content compared to the control.

Interaction treatments of vermicompost at the rate of 8 m³/fed., combined with 15 kg/fed. CaSiO₃ increased significantly in the above mentioned traits (plant growth, essential oil determinations). Also, the same treatment gave the highest values of the Terpinen-4-ol and Limonene. While the combination between 8 m³/fed vermicompost and CaSiO₃ 20 kg/fed showed the highest values of the β-Phyllandrene content. Also, the highest values of the Linalool was obtained in the plants which treated by 10 m³/fed vermicompost and CaSiO₃ at 15 kg/fed. In addition that, the highest total carbohydrates%, nitrogenase and dehydrogenase activities and nutrient contents of N, P, K and Ca were recorded with 8 m³/fed. of vermicompost and CaSiO₃ at 15 kg/fed. On the opposite, the all tested treatments gave the lowest proline and Na content compared to the control.

Key words: Majorana hortensis L., vermicompost, calcium silicate, Terpinen-4-ol, β-Phyllandrene chemical composition and essential oil components.
